and read from the body. This approach can make your endpoints more readable if you find that they're getting a bit unwieldy.

TIP In chapter 16 you'll learn about model binding in MVC and Razor Pages. You'll be pleased to know that in those cases, the `[AsParameters]` approach works out of the box without the need for an extra attribute.

That brings us to the end of this section on model binding. If all went well, your endpoint handler's arguments are created, and the handler is ready to execute its logic. It's time to handle the request, right? Nothing to worry about.

Not so fast! How do you know that the data you received was valid? How do you know that you haven't been sent malicious data attempting a SQL injection attack or a phone number full of letters? The binder is relatively blindly assigning values sent in a request, which you're happily going to plug into your own methods. What stops nefarious little Jimmy from sending malicious values to your application? Except for basic safeguards, nothing is stopping him, which is why it's important that you *always* validate the input coming in. ASP.NET Core provides a way to do this in a declarative manner out of the box, which is the focus of section 7.10.

7.10 Handling user input with model validation

In this section, I discuss the following topics:

- What validation is and why you need it
