In chapter 8 we leave minimal APIs behind to look at dependency injection in ASP.NET Core and see how it helps create loosely coupled applications. You'll learn how to register the ASP.NET Core framework services with a container, add your own services, and manage service lifetimes.

Summary

- Model binding is the process of creating the arguments for endpoint handlers from the details of an HTTP request. Model binding takes care of extracting and parsing the strings in the request so that you don't have to.
- Simple values such as `int`, `string`, and `double` can bind to route values, query string values, and headers. These values are common and easy to extract from the request without any manual parsing.
- If a simple value fails to bind because the value in the request is incompatible with the handler parameter, a `BadHttpRequestException` is thrown, and a `400 Bad Request` response is returned.
- You can turn a custom type into a simple type by adding a `TryParse` method with the signature `bool TryParse(string value, out T result)`. If you return `false` from this method, minimal APIs will return a `400 Bad Request` response.
- Complex types bind to the request body by default by deserializing from JSON. Minimal APIs can bind only to JSON bodies; you can't use model binding to access form values.
