❶ The endpoint is called when a new user is created.

❷ The IEmailSender is injected into the handler using DI.

❸ The handler uses the IEmailSender instance.

The final step in making the refactoring work is configuring your services with the DI container. This configuration lets the DI container know what to use when it needs to fulfill the `IEmailSender` dependency. If you don't register your services, you'll get an exception at runtime, like the one in figure 9.1. This exception describes a model-binding problem; the minimal API infrastructure tries to bind the `emailSender` parameter to the request body because `IEmailSender` isn't a known service in the DI container.
