providers overwrite configuration values with the same keys from earlier providers.

Update your code to load configuration from three different configuration providers—two JSON providers and an environment variable provider—by adding them to `ConfigurationManager` as shown in the following listing.

Listing 10.4 Loading from multiple providers in Program.cs

```
WebApplicationBuilder builder = WebApplication.CreateBuilder(args);

builder.Configuration.Sources.Clear();
builder.Configuration                                          ❶
    .AddJsonFile("sharedSettings.json", optional: true);       ❶
builder.Configuration.AddJsonFile("appsettings.json", optional: true);
builder.Configuration.AddEnvironmentVariables();               ❷

WebApplication app = builder.Build();

app.MapGet("/", () => app.Configuration.AsEnumerable());

app.Run();
```

❶ Loads configuration from a different JSON configuration file before the appsettings.json file

❷ Adds the machine's environment variables as a configuration provider

This layered design can be useful for several things. Fundamentally, it allows you to aggregate configuration values from multiple sources into a single, cohesive object. To cement this design in place, consider the configuration values in figure 10.4.
