- If you want to reload your POCO options objects when your configuration changes, use the `IOptionsSnapshot<T>` interface instead. These instances are registered in DI with a scoped lifetime, so they're re-created for every request. Using the `IOptionsSnapshot<T>` interface has performance implications due to binding to the options object repeatedly, so use it only when that cost is acceptable.
- Applications running in different environments, such as development versus production, often require different configuration values. ASP.NET Core determines the current hosting environment by using the `ASPNETCORE_ENVIRONMENT` environment variable. If this variable isn't set, the environment is assumed to be production.
- You can set the hosting environment locally by using the launchSettings.json file, which allows you to scope environment variables to a specific project.
- The current hosting environment is exposed as an `IHostEnvironment` interface. You can check for specific environments by using `IsDevelopment()`, `IsStaging()`, and `IsProduction()`. Then you can use the `IHostEnvironment` object to load files specific to the current environment, such as appsettings.Production.json.
