As with the generic web page example, the request process starts when a user's browser sends an HTTP request to the server, as shown in figure 1.3.

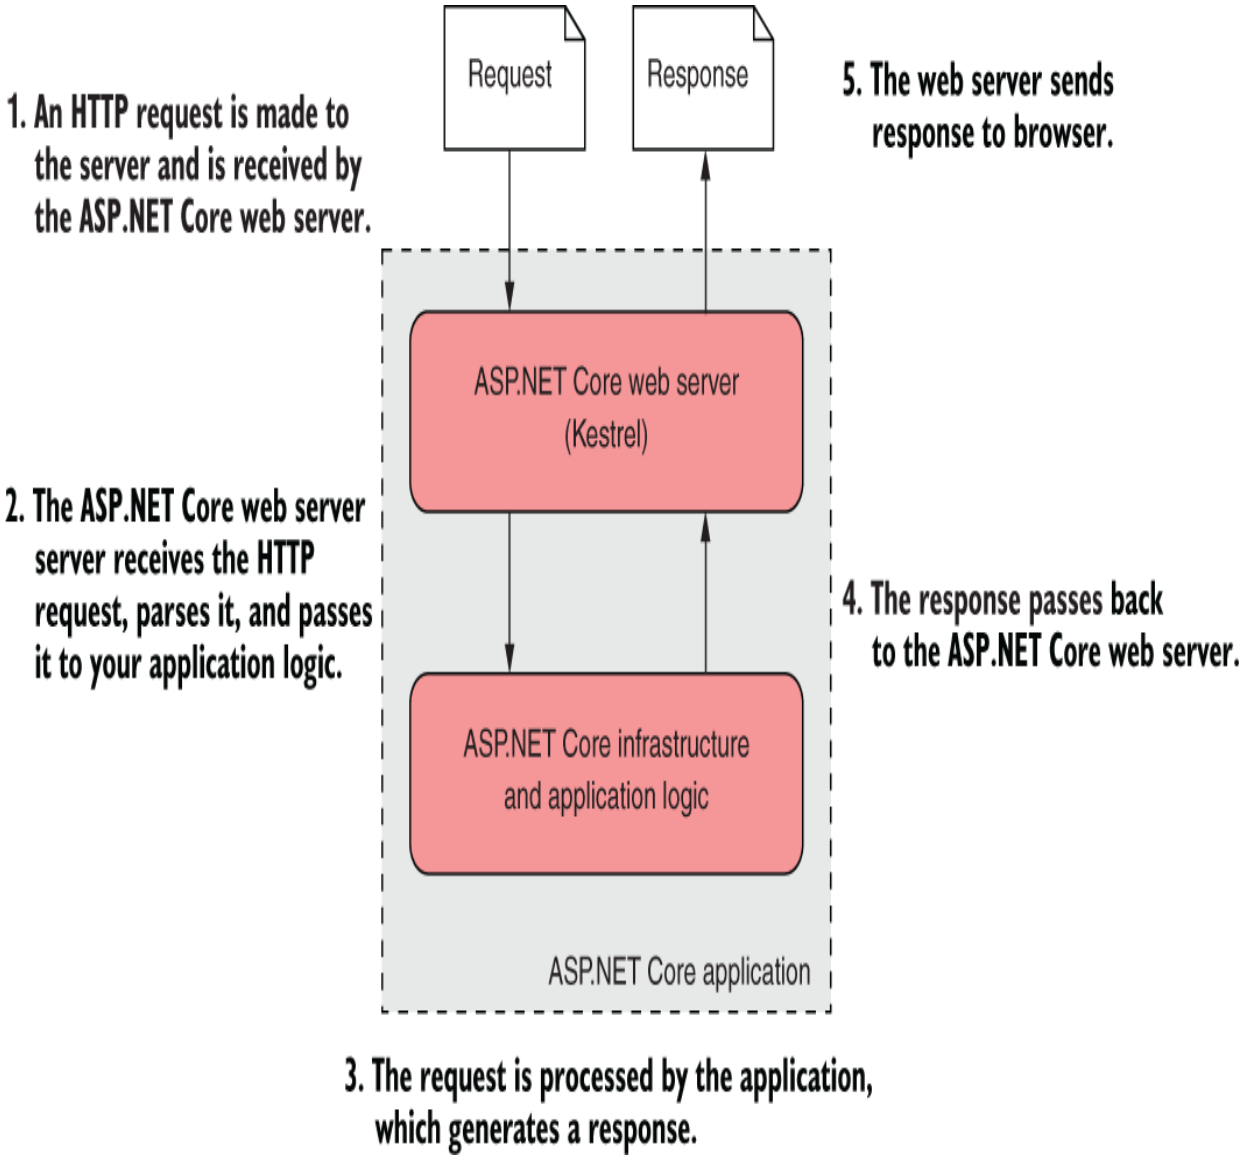

Figure 1.3 How an ASP.NET Core application processes a request. A request is received by the ASP.NET Core application, which runs a self-hosted web server. The web server processes the request and passes it to the body of the application, which generates a response and returns it to the web server. The web server sends this response to the browser.
