This command creates three files in the Migrations folder in your project:

- *Migration file*—This file, with the Timestamp_MigrationName.cs format, describes the actions to take on the database, such as creating a table or adding a column. Note that the commands generated here are database-provider-specific, based on the database provider configured in your project.
- *Migration designer.cs file*—This file describes EF Core's internal model of your data model at the point in time when the migration was generated.
- *AppDbContextModelSnapshot.cs*—This file describes EF Core's current internal model. This file is updated when you add another migration, so it should always be the same as the current (latest) migration. EF Core can use AppDbContextModelSnapshot.cs to determine a database's previous state when creating a new migration without interacting with the database directly.

These three files encapsulate the migration process, but adding a migration doesn't update anything in the database itself. For that task, you must run a different command to apply the migration to the database.

TIP You can, and should, look inside the migration file EF Core generates to check what it will do to your database before running the following commands. Better safe than sorry!

You can apply migrations in any of four ways:

- Using the .NET tool
- Using the Visual Studio PowerShell cmdlets
