NOTE The binding model for Razor Pages is conceptually equivalent to all the parameters you pass in to a minimal API endpoint that are populated from the request.

The binding model in this case corresponds to the method parameter of the `OnGet` page handler. An instance of the Razor Page is created using its constructor, and the binding model is passed to the page handler when it executes, so it can be used to decide how to respond. For this example, the page handler uses it to decide which to-do items to display on the page.

13.4.2 Executing a handler using the application model

The role of the page handler as the controller in the MVC pattern is to coordinate the generation of a response to the request it's handling. That means it should perform only a limited number of actions. In particular, it should

- Validate that the data contained in the binding model is valid for the request.
- Invoke the appropriate actions on the application model using services.
- Select an appropriate response to generate based on the response from the application model.

Figure 13.10 shows the page handler invoking an appropriate method on the application model. Here, you can see that the application model is a somewhat-abstract concept that encapsulates the remaining non-UI parts of your application. It contains the *domain model*, several services, and the database interaction.
