Note that this directive includes the `"/"` at the start of the route, indicating that this is a *custom* route template, instead of an *addition*. The route template for this page will be `"{category}/{name}"` no matter which Razor Page it is applied to.

Similarly, you can create a static custom template for a page by starting the template with a `"/"` and using only literal segments:

```
@page "/checkout"
```

Wherever you place your checkout Razor Page within the Pages folder, using this directive ensures that it always has the route template `"checkout"`, so it always matches the request URL `/checkout`.

TIP You can also think of custom route templates that start with "/" as *absolute* route templates, whereas other route templates are *relative* to their location in the file hierarchy.

It's important to note that when you customize the route template for a Razor Page, both when appending to the default and when replacing it with a custom route, the *default template is no longer valid*. If you use the `"checkout"` route template above on a Razor Page located at `Pages/Payment.cshtml`, you can access it only by using the URL `/checkout`; the URL `/Payment` is no longer valid and won't execute the Razor Page.

TIP Customizing the route template for a Razor Page using the `@page` directive replaces the default route template for the page. In section 14.6 I show how you can add extra routes while preserving the default route template.
