DEFINITION If a page handler does not match a request's HTTP verb and handler value, an *implicit* page handler is executed that renders the associated Razor view. Implicit page handlers take part in model binding and use page filters but execute no logic.

There's one exception to the implicit page handler rule: if a request uses the `HEAD` verb, and there is no corresponding `OnHead` handler, the `EndpointMiddleware` executes the `OnGet` handler instead (if it exists).

NOTE `HEAD` requests are typically sent automatically by the browser and don't return a response body. They're often used for security purposes, as you'll see in chapter 28.

Now that you know how a page handler is selected, you can think about how it's executed.

15.3 Accepting parameters to page handlers

In chapter 7 you learned about the intricacies of model binding in minimal API endpoint handlers. Like minimal APIs, Razor Page page handlers can use model binding to easily extract values from the request. You'll learn the details of Razor Page model binding in chapter 16; in this section you'll learn about the basic mechanics of Razor Page model binding and the basic options available.

When working with Razor Pages, you'll often want to extract values from an incoming request. If the request is for a search page, the request might contain the search term and the page number in the query string. If the request is `POST`ing a form to your application, such as a user logging in
