In the next section we'll look in more depth at some of the common `IActionResult` types.

15.4 Returning IActionResult responses

In the previous section, I emphasized that page handlers decide what type of response to return, but they don't generate the response themselves. It's the `IActionResult` returned by a page handler that, when executed by the Razor Pages infrastructure using the view engine, generates the response.

WARNING Note that the interface type is `IActionResult` *not* `IResult`. `IResult` is used in minimal APIs and should generally be avoided in Razor Pages (and MVC controllers). In .NET 7, `IResult` types returned from Razor Pages or MVC controllers execute as expected, but they don't have all the same features as `IActionResult`, so you should favor `IActionResult` in Razor Pages.

`IActionResult`s are a key part of the MVC design pattern. They separate the decision of what sort of response to send from the generation of the response. This allows you to test your action method logic to confirm that the right sort of response is sent for a given input. You can then separately test that a given `IActionResult` generates the expected HTML, for example.

ASP.NET Core has many types of `IActionResult`, such as

- `PageResult`—Generates an HTML view for the associated page in Razor Pages and returns a `200` HTTP response.
