and modify its internal state. ASP.NET Core has multiple models, which takes the single-responsibility principle (SRP) one step further than some views of MVC.

In chapter 13 we looked at an example of a to-do list application that can show all the to-do items for a given category and username. With this application, you make a request to a URL that's routed using `todo/listcategory/{category}/{username}`. This returns a response showing all the relevant to-do items, as shown in figure 16.1.

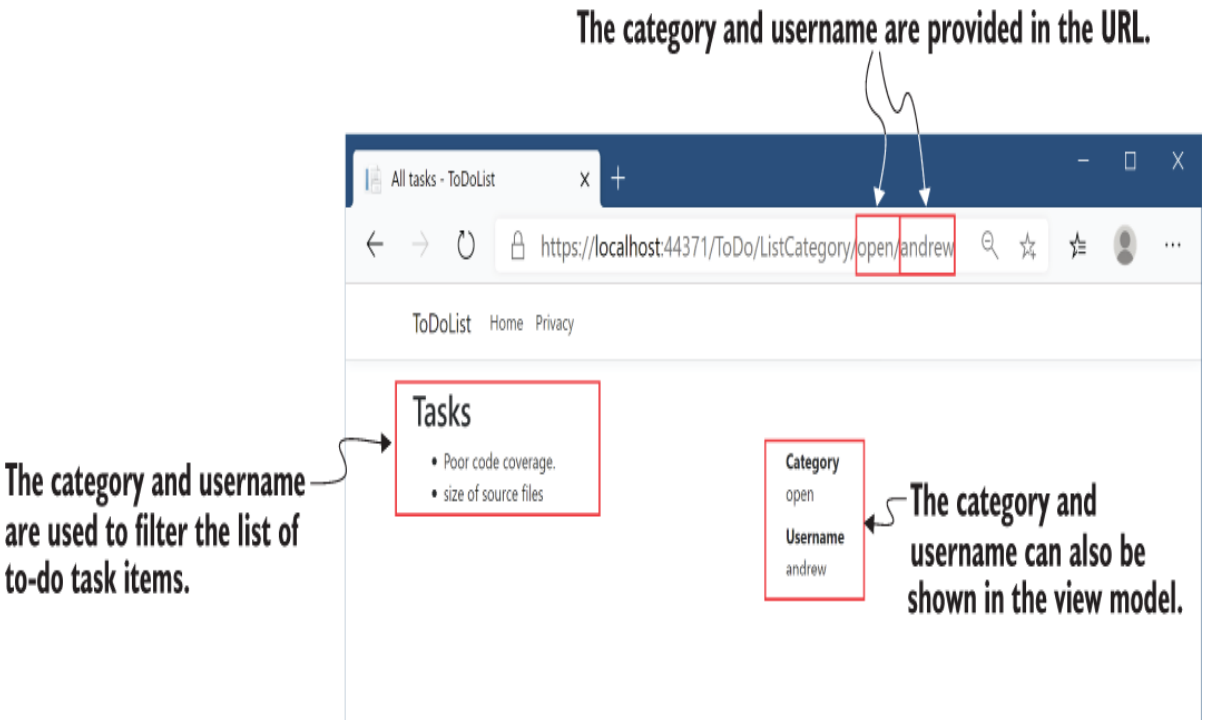

Figure 16.1 A basic to-do list application that displays to-do list items. A user can filter the list of items by changing the `category` and `username` parameters in the URL.

The application uses the same MVC constructs you've already seen, such as routing to a Razor Page handler, as well as various models. Figure 16.2 shows how a request to this application maps to the MVC design pattern and how it
