- *Query string values*—Passed at the end of the URL, not used during routing

WARNING Even though conceptually similar, the Razor Page binding process works quite differently from the approach used by minimal APIs.

The model binding process for Razor Pages is shown in figure 16.3. The model binder checks each binding source to see whether it contains a value that could be set on the model. Alternatively, the model can choose the specific source the value should come from, as you'll see in section 16.2.3. Once each property is bound, the model is validated and is set as a property on the `PageModel` or passed as a parameter to the page handler. You'll learn about the validation process in the second half of this chapter.
