Route values aren't the only values the Razor Pages model binder can use to create your binding models. As you saw previously, the framework will look through three default binding sources to find a match for your binding models:

- Form values
- Route values
- Query string values

Each of these binding sources store values as name-value pairs. If none of the binding sources contains the required value, the binding model is set to a new, default instance of the type instead. The exact value the binding model will have in this case depends on the type of the variable:

- For value types, the value will be `default(T)`. For an `int` parameter this would be `0`, and for a `bool` it would be `false`.
- For reference types, the type is created using the default (parameterless) constructor. For custom types like `ProductModel`, that will create a new object. For nullable types like `int?` or `bool?`, the value will be `null`.
- For string types, the value will be `null`.

WARNING It's important to consider the behavior of your page handler when model binding fails to bind your method parameters. If none of the binding sources contains the value, the value passed to the method could be `null` or could unexpectedly have a default value (for value types).

Listing 16.2 showed how to bind a single method parameter. Let's take the next logical step and look at how you'd bind multiple method parameters.

Let's say you're building a currency converter application. As the first step you need to create a method in which the user provides a value in one currency, and you must convert it to another. You first create a Razor Page called
