- `currencies[index]`—Where `currencies` is the name of the parameter to bind and `index` is the index of the item to bind, such as `currencies[0]=GBP&currencies[1]=USD`.
- `[index]`—If you're binding to a single list (as in this example), you can omit the name of the parameter, such as `[0]=GBP&[1]=USD`.
- `currencies`—Alternatively, you can omit the `index` and send `currencies` as the key for every value, such as `currencies=GBP&currencies=USD`.

The key values can come from route values and query values, but it's far more common to `POST` them in a form. Dictionaries can use similar binding, where the dictionary key replaces the index both when the parameter is named and when it's omitted.

TIP In the previous example I showed a collection using the built-in `string` type, but you can also bind collections of complex type, such as a `List<UserBindingModel>`.

If this all seems a bit confusing, don't feel too alarmed. If you're building a traditional web application and using Razor views to generate HTML, the framework will take care of generating the correct names for you. As you'll see in chapter 18, the Razor view ensures that any form data you `POST` is generated in the correct format.

Binding file uploads with IFormFile

Razor Pages supports users uploading files by exposing the `IFormFile` and `IFormFileCollection` interfaces. You can use these interfaces as
