NOTE The purpose of this example is to highlight the model-binding approach. The code is overly simple from a logic point of view. For example, it doesn't check that the product with the provided ID exists or include any error handling.

This form shows several patterns related to model binding that I try to adhere to when building Razor Pages:

- *Bind only a single property with* `[BindProperty]`. I favor having a single property decorated with `[BindProperty]` for model binding in general. When more than one value needs to be bound, I create a separate class, `InputModel`, to hold the values, and I decorate that single property with `[BindProperty]`. Decorating a single property like this makes it harder to forget to add the attribute, and it means all your Razor Pages use the same pattern.
- *Define your binding model as a nested class*. I define the `InputModel` as a nested class inside my Razor Page. The binding model is normally highly specific to that single page, so doing this keeps everything you're working on together. Additionally, I normally use that exact class name, `InputModel`, for all my pages. Again, this adds consistency to your Razor Pages.
