Summary

- Razor Pages uses three distinct models, each responsible for a different aspect of a request. The binding model encapsulates data sent as part of a request. The application model represents the state of the application. The `PageModel` is the backing class for the Razor Page, and it exposes the data used by the Razor view to generate a response.
- Model binding extracts values from a request and uses them to create .NET objects the page handler can use when they execute. Any properties on the `PageModel` marked with the `[BindProperty]` attribute and method parameters of the page handlers will take part in model binding.
- By default, there are three binding sources for Razor Pages: `POST`ed form values, route values, and the query string. The binder will interrogate these sources in order when trying to bind your binding models.
- When binding values to models, the names of the parameters and properties aren’t case-sensitive.
- You can bind to simple types or to the properties of complex types. Simple types must be convertible from strings to be bound automatically, such as numbers, dates, Boolean values, and custom types with a `TryParse` method.
- To bind complex types, the types must have a default constructor and public, settable properties. The Razor Pages model binder binds each property of a complex type using values from the binding sources.
