In this chapter we'll be focusing primarily on displaying data and generating HTML using Razor rather than creating forms. You'll see how to render values from your `PageModel` to the HTML, and how to use C# to control the generated output. Finally, you'll learn how to extract the common elements of your views into subviews called *layouts* and *partial views*, and how to compose them to create the final HTML page.

17.1 Views: Rendering the user interface

In this section I provide a quick introduction to rendering HTML using Razor views. We'll recap the MVC design pattern used by Razor Pages and where the view fits in. Then I'll show how Razor syntax allows you to mix C# and HTML to generate dynamic UIs.

As you know from earlier chapters on the MVC design pattern, it's the job of the Razor Page's page handler to choose what to return to the client. For example, if you're developing a to-do list application, imagine a request to view a particular to-do item, as shown in figure 17.1.
