In ASP.NET Core, you have several ways of passing data from a page handler in a Razor Page to its view. Which approach is best depends on the data you're trying to pass through, but in general you should use the mechanisms in the following order:

- `PageModel` *properties*—You should generally expose any data that needs to be displayed as properties on your `PageModel`. Any data that is specific to the associated Razor view should be exposed this way. The `PageModel` object is available in the view when it's rendered, as you'll see shortly.
- `ViewData`—This is a dictionary of objects with `string` keys that can be used to pass arbitrary data from the page handler to the view. In addition, it allows you to pass data to *layout* files, as you'll see in section 17.4. Layout files are the main reason for using `ViewData` instead of setting properties on the `PageModel`.
- `TempData`—`TempData` is a dictionary of objects with `string` keys, similar to `ViewData`, that is stored until it's read in a different request. This is commonly used to temporarily persist data when using the POST-REDIRECT-GET pattern. By default `TempData` stores the data in an encrypted cookie, but other storage options are available, as described in the documentation at http://mng.bz/Wzx1.
- `HttpContext`—Technically, the `HttpContext` object is available in both the page handler and Razor view, so you could use it to transfer data between them. But don't—there's no need for it with the other methods available to you.
