Razor templates HTML-encode C# expressions before they're written to the output stream. This is primarily for security reasons; writing out arbitrary strings to your HTML could allow users to inject malicious data and JavaScript into your website. Consequently, the C# variables you print in your Razor template get written as HTML-encoded values.

NOTE Razor also renders non-ASCII Unicode characters, such as `ó` and `è`, as HTML entities: `ó` and `è`. You can customize this behavior using `WebEncoderOptions` in Program.cs, as in this example: `builder.Services .Configure<WebEncoderOptions> (o => o.AllowCharacter('ó')).`

In some cases, you might need to directly write out HTML contained in a `string` to the response. If you find yourself in this situation, first, stop. Do you *really* need to do this? If the values you're writing have been entered by a user, or were created based on values provided by users, there's a serious risk of creating a security hole in your website.

If you really need to write the variable out to the HTML stream, you can do so using the `Html` property on the view page and calling the `Raw` method:

```
<li>@Html.Raw(task)</li>
```

With this approach, the string in `task` is directly written to the output stream, without encoding, producing the HTML you originally wanted, `<li> <strong>Check oil</strong> </li>`, which renders as shown in figure 17.8.
