In chapter 1, I described how a browser makes an HTTP request to a server and receives a response, which it uses to render HTML on the page. ASP.NET Core allows you to generate that HTML dynamically depending on the particulars of the request, so that (for example) you can display different data depending on the current logged-in user.

Suppose that you want to create a web app to display information about your company. You could create a simple ASP.NET Core app to achieve this goal; later, you could add dynamic features to your app. Figure 3.1 shows how the application would handle a request for a page in your application.
