- ASP.NET Core 3.0 onwards uses System.Text.Json, which is a strict, high performance library for JSON serialization and deserialization. You can replace this serializer with the common Newtonsoft.Json formatter by calling `AddNewtonsoftJson()` on the return value from `services.AddControllers()`.
- Content negotiation occurs when the client specifies the type of data it can handle and the server chooses a return format based on this. It allows multiple clients to call your API and receive data in a format they can understand.
- By default, ASP.NET Core can return `text/plain`, `text/html`, and `application/ json`, but you can add formatters if you need to support other formats.
- You can add XML formatters by calling `AddXmlSerializerFormatters()` on the return value from `services.AddControllers()` in your `Startup` class. These can format the response as XML, as well as receive XML in a request body.
- Content negotiation isn't used when the `Accept` header contains `*/*`, such as in most browsers. Instead, your application uses the default formatter, JSON. You can disable this option by setting the `RespectBrowserAcceptHeader` option to `true` when adding your controller services in Program.cs.
- You can mix web API Controllers and minimal API endpoints in the same application, but you may find it easier to use one or the other.
