demonstrate, I'm going to create two custom filters for `RecipeApiController`:

- `ValidateModelAttribute`—This will return `BadRequestResult` if the model state indicates that the binding model is invalid and will short-circuit the action execution. This attribute used to be a staple of my web API applications, but the `[ApiController]` attribute now handles this (and more) for you. Nevertheless, I think it's useful to understand what's going on behind the scenes.
- `EnsureRecipeExistsAttribute`—This uses each action method's `id` argument to validate that the requested `Recipe` entity exists before the action method runs. If the `Recipe` doesn't exist, the filter returns `NotFoundResult` and short-circuits the pipeline.

As you saw in chapter 16, the MVC framework automatically validates your binding models before executing your actions and Razor Page handlers, but it's up to you to decide what to do about it. For web API controllers, it's common to return a `400 Bad Request` response containing a list of the errors, as shown in figure 22.1.
