If you apply this action filter to your `RecipeApiController`, you can remove this code from the start of both the action methods, as it will run automatically in the filter pipeline:

```
if (!ModelState.IsValid)
{
    return BadRequest(ModelState);
}
```

You'll use a similar approach to remove the duplicate code that checks whether the `id` provided as an argument to the action methods corresponds to an existing Recipe entity.

The following listing shows the `EnsureRecipeExistsAttribute` action filter. This uses an instance of `RecipeService` to check whether the `Recipe` exists and returns a `404 Not Found` if it doesn't.

Listing 22.6 An action filter to check whether a `Recipe` exists

```
public class EnsureRecipeExistsAtribute : ActionFilterAttribute
{
    public override void OnActionExecuting(
        ActionExecutingContext context)
    {
        var service = context.HttpContext.RequestServices    ❶
            .GetService<RecipeService>();                    ❶
        var recipeId = (int) context.ActionArguments["id"];  ❷
        if (!service.DoesRecipeExist(recipeId))              ❸
        {
            context.Result = new NotFoundResult();           ❹
        }
    }
}
```

❶ Fetches an instance of RecipeService from the DI container

❷ Retrieves the id parameter that will be passed to the action method when it executes

❸ Checks whether a Recipe entity with the given RecipeId exists
