If everything runs successfully in the pipeline, and there's no short-circuiting, the next stage of the pipeline after action filters is result filters. These run before and after the `IActionResult` returned by the action method (or action filters) is executed.

WARNING If the pipeline is short-circuited by setting `context.Result`, the result filter stage won't run, but the `IActionResult` will still be executed to generate the response. The exceptions to this rule are action and page filters, which only short-circuit the action execution, as you saw in chapter 21. Result filters run as normal, as though the action or page handler itself generated the response.

Result filters run immediately after action filters, so many of their use cases are similar, but you typically use result filters to customize the way the `IActionResult` executes. For example, ASP.NET Core has several result filters built into its framework:

- `ProducesAttribute`—This forces a web API result to be serialized to a specific output format. For example, decorating your action method with `[Produces ("application/xml")]` forces the formatters to try to format the response as XML, even if the client doesn't list XML in its `Accept` header.
