- `FormatFilterAttribute`—Decorating an action method with this filter tells the formatter to look for a route value or query string parameter called `format` and to use that to determine the output format. For example, you could call `/api/recipe/11?format=json` and `FormatFilter` will format the response as JSON or call `api/recipe/11?format=xml` and get the response as XML.

NOTE Remember that you need to explicitly configure the XML formatters if you want to serialize to XML, as described in chapter 20. For details on formatting results based on the URL, see my blog entry on the topic: http://mng.bz/1rYV.

As well as controlling the output formatters, you can use result filters to make any last-minute adjustments before `IActionResult` is executed and the response is generated.

As an example of the kind of flexibility available, in the following listing I demonstrate setting the `LastModified` header, based on the object returned from the action. This is a somewhat contrived example—it's specific enough to a single action that it likely doesn't warrant being moved to a result filter—but I hope you get the idea.

Listing 22.9 Setting a response header in a result filter

```
public class AddLastModifedHeaderAttribute : ResultFilterAttribute    ❶
{
    public override void OnResultExecuting(                           ❷
        ResultExecutingContext context)                               ❷
    {
        if (context.Result is OkObjectResult result                   ❸
            && result.Value is RecipeDetailViewModel detail)          ❹
        {
```
