

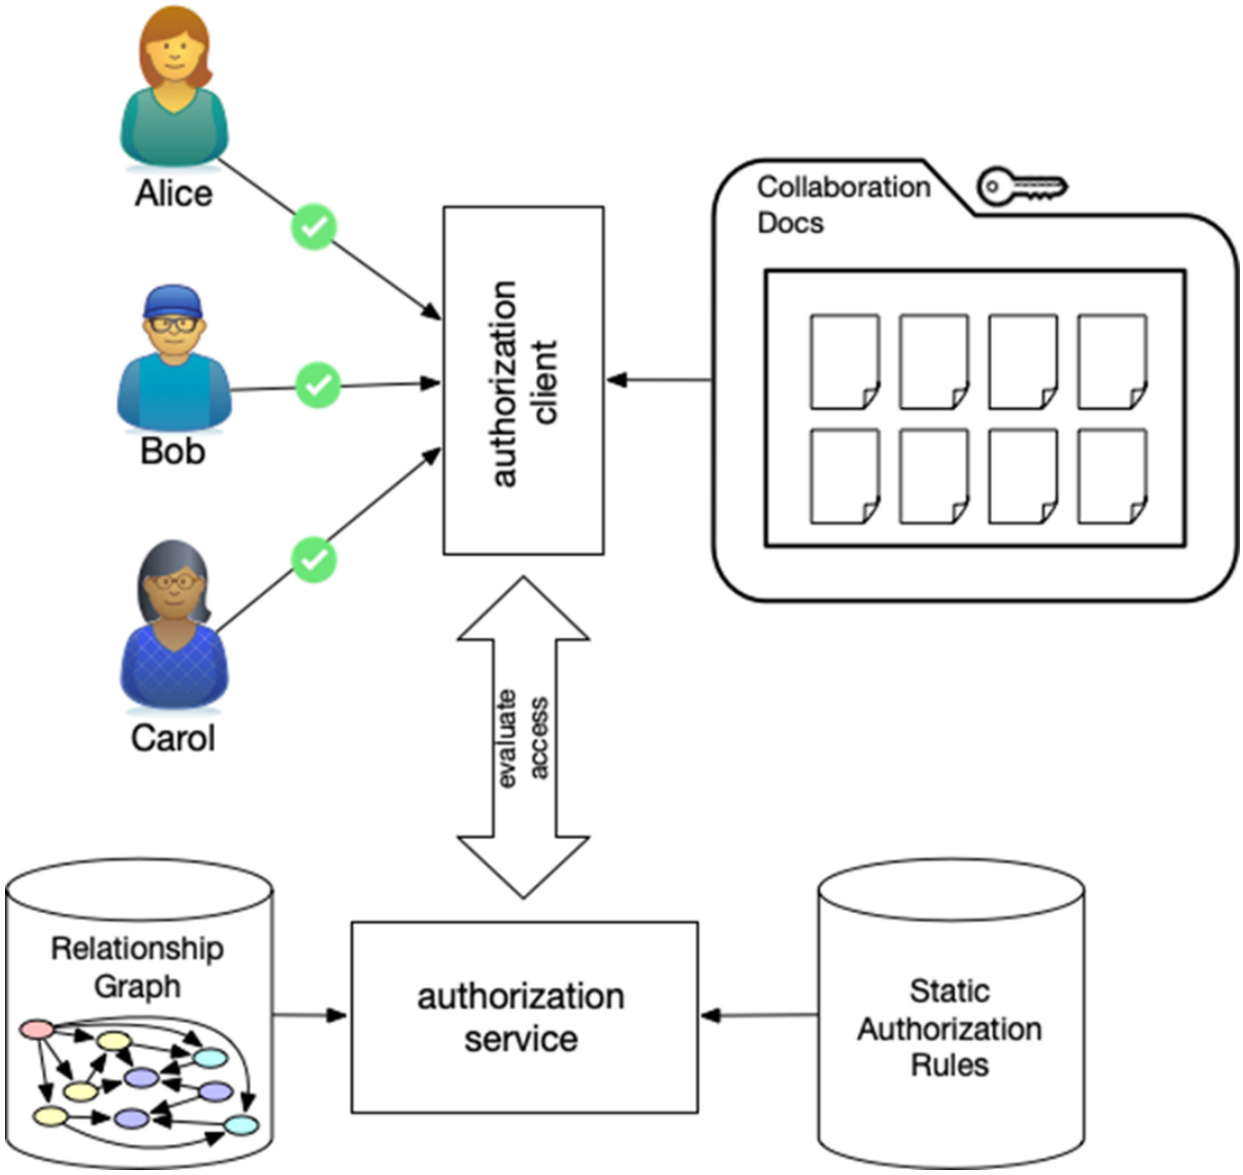

Figure 6.2 Relationship-based authorization using graph traversal and policy evaluation. Access is determined by analyzing relationships between principals and resources.

ACME has written a number of static rules for the authorization service that govern access by both employees and customers. Here are some examples:

```
permit view when principal has "viewer" or "owner" relationship to r
esource
permit view, update when principal has "editor" relationship to reso
urce
permit all when principal has "owner" relationship to resource
permit all when principal is "manager" of an "owner" of the resource
```
