```
when {
  context.requestTime < datetime("2025-12-31T23:59:59Z")
  && context.requestAge < duration("30d")
}
```

This condition requires that the request occur before the end of 2025 and within the past 30 days.

IP CONSTRAINTS

Authorization policies often assess the sources and destinations of requests, which are identified by IP addresses. Here's an example of a policy condition using IP operators.

```
when {
  ip(context.clientIp) in ip("10.0.0.0/16")
}
```

This condition is true when the `clientIP` belongs to the 10.0.x.x internal network. Note that the `ip()` operator constructs the range from the CIDR block specification.

7.4.6 Safe and analyzable by design

Cedar strikes a careful balance between expressiveness, speed, and auditability. Its design emphasizes features that make it both powerful and trustworthy, starting with performance, safety, and analyzability.

PERFORMANCE

Cedar is engineered for sub-millisecond policy evaluation—even when processing hundreds or thousands of policies. It accomplishes this through efficient scope filtering and a compact evaluation model that avoids costly operations. In one benchmark, Cedar consistently made decisions in under 1ms across a large policy set.
