This schema gives ACME's identity team a clear, enforceable model of their authorization environment, along with a shared vocabulary on which all policies will depend.

9.2.2 How schema shapes policies

With this schema in place:

- The owner attribute of a Document must refer to an Employee.
- You can't accidentally write a policy that allows a customer to `doc:edit`. The schema prevents it.
- The `context.device.managed` attribute is included in every request, enabling ABAC-style conditions without needing to repeat structure in each policy.

By restricting what policies can reference, the schema ensures ACME's authorization logic remains aligned with real-world rules, decreasing both accidental over-permissiveness and policy drift over time.

9.2.3 Updating schema as your system evolves

Schemas are living documents. When ACME later introduced a Folder entity to organize documents, they first updated the schema and then created new policies. This order—update schema → write policies → test—ensures that authorization changes stay safe and predictable.
