```
permit(
    principal in ACME::Team::"team:legal",
    action in [ACME::"doc:view", ACME::"doc:edit"],
    resource in ACME::Document
)
when { resource.classification == "Legal" };
```

By scoping the principal to `ACME::Team::"team:legal"`, we eliminate the need for an extra condition in the `when` clause and make the policy's purpose clear at a glance. This also means the entity store only needs to answer "is this principal a member of the Legal team?" without checking any per-document attributes.

> ***NOTE***
>
> While constructions like `principal in […]` are not allowed, using principal in `ACME::Team::"team:legal"` is fine because `ACME::Team::"team:legal"` refers to a single entity, not an entity union denoted by the brackets.

### 9.5.3 Relationship permissions

Relationship permissions (ReBAC) grant access based on the connections between principals and resources. The "manager of owner" rule from ACME's core policies is a perfect example.

```
permit(
    principal in ACME::Employee,
    action in [ACME::"doc:view", ACME::"doc:edit"],
    resource in ACME::Document
)
when { resource.owner.manager == principal };
```

This policy doesn't mention teams at all; it relies on the manager relationship from the entity store to determine access dynamically.
