- **Split ownership**—the central identity team manages templates, and product teams supply parameters within defined limits.
- **Provide escape hatches**—combine templates with specific overrides when a workspace or customer needs a more precise or flexible rule without creating a separate template.

When done well, templates maintain your policy set's consistency and scalability while still allowing for precise, auditable differences where the business truly needs them.

9.7.2 Overrides

Sometimes, the template isn't enough for every situation. ACME uses overrides for special cases like the following:

- A customer with stricter requirements might `forbid` all sharing, even by owners.
- A project team might need to grant external contractors temporary editing rights.

Overrides are simply additional Cedar policies added alongside the template-generated policies. Since Cedar reviews all relevant policies together, an override can safely make rules stricter or more lenient without changing the original template.

This differs from layering global constraints in several key ways:

- **Overrides** are local exceptions—they apply to a specific resource, workspace, or customer, and usually have a limited scope. They are often written by delegated administrators or product teams.
- **Global constraints** are organization-wide guardrails; they apply everywhere, regardless of local policy, and are usually managed by the central identity team.

An example where an override might be useful is when ACME needs to restrict a template rule for a specific workspace. Imagine the `document-view-template` usually allows the owner's `readers` team to view any
