document. For a sensitive workspace, an override can prevent all viewing unless the principal is the owner.

```
// added to #override document-view-template to restrict legal works
pace
forbid(
    principal in ACME::Employee,
    action == ACME::Action::"doc:view",
    resource in ACME::Document::"workspace:legal-review"
)
when { resource.owner != principal };
```

Here, the override acts as a local guardrail, further restricting access for a single workspace without altering the global template. Note the comment that makes it clear this is an override. The `#override` tag makes it easy to find overrides when searching the policy store.

Templates promote consistency and reduce boilerplate code. Overrides let you handle exceptions without changing the base rules. In contrast, global constraints make sure that specific rules are never skipped anywhere in the system.

9.8 Mapping requests to Cedar evaluations

For Cedar to make an authorization decision, your application or API gateway must convert a real-world request into the three parts Cedar expects: principal, action, and resource, along with any context. This is the role of the Policy Enforcement Point (PEP)—the component that intercepts the request, gathers the evaluation data, and sends it to Cedar's decision API.

At ACME, the Customer Collaboration service's PEP wraps each document request in a call to Cedar. When a user clicks Share in the UI, it triggers a process similar to the one shown in figure 9.2.
