Pros:

- No infrastructure needed; AWS handles scaling, updates, and availability.
- Integrated with other AWS services for identity, logging, and monitoring.
- Helpful for managing multi-account AWS environments.

Cons:

- Network latency for each evaluation depends on your application's proximity to AWS.
- An AWS account is required.
- Policies and data are stored in AWS-managed storage, which reduces your control over hosting.

**Hybrid deployments**

Some organizations combine both approaches: running Cedar Local Agent in their own environment for low-latency decisions while storing and managing policies in AVP. In this setup, AVP serves as the primary source of truth for policies and entities, and the Local Agent periodically syncs updates. This method merges the operational convenience of AWS-managed policy hosting with the performance and flexibility of local evaluation.

At ACME, the Customer Collaboration platform uses the Cedar Local Agent for low-latency, on-premises deployments, and AVP for customer-facing SaaS instances hosted entirely in AWS. The policy code is the same; the difference is where and how the evaluation runs.

**Cederling**

Cedarling is an open-source project from the Linux Foundation Janssen Project that turns the Cedar evaluation engine into a full-featured policy decision point (PDP) that applications can embed directly. You can find it at https://github.com/JanssenProject/jans/wiki/Cedarling-Project-Overview#cedarling-project-overview. Like the Cedar Local Agent (CLA)
