and Amazon Verified Permissions (AVP), Cedarling uses the same Cedar core, but it emphasizes JWT-driven, in-process evaluation.

Cedarling validates JSON Web Tokens (JWTs), maps claims into Cedar entities, and enforces policies via the `Cedarling::authorize` method. It also performs other PDP functions such as logging, policy store management, workload identity registration, and communication with enterprise IT infrastructure. An in-memory key–value store with automatic record expiration supports these services, enabling sub-100ms evaluations.

Pros

- Direct JWT integration; claims are automatically mapped to Cedar entities.
- Local, low-latency evaluation without relying on a remote service.
- Embedded PDP functions (logging, policy store, workload registration).
- Works with any system that issues JWTs.

Cons

- Early-stage project, under active development.
- Integration requires handling Cedarling's configuration and entity mapping.

Together, CLA, AVP, and Cedarling illustrate Cedar's portability, from AWS-managed services to sidecars in microservices to JWT-aware applications.

9.9 From concept to policy

We have now progressed from the concepts of Cedar introduced earlier to the practical work of modeling schemas, authoring policies, and conducting evaluations. We observed how ACME's Customer Collaboration platform
