

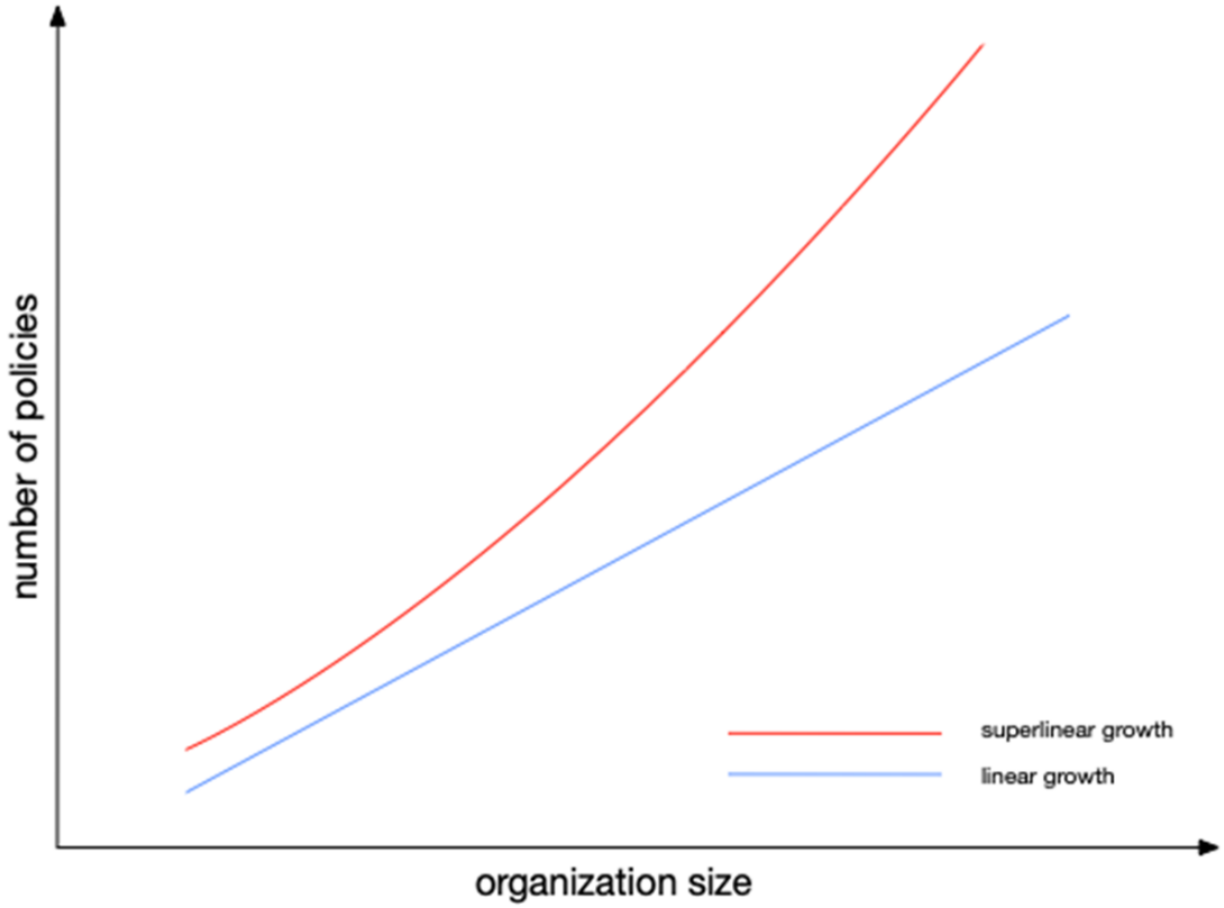

Figure 1.4 As an organization grows, the number of access policies tends to increase faster than linearly. Though a small organization might manage with a simple, flat set of policies, larger organizations face compounding complexity due to team structures, regional compliance, and overlapping responsibilities, leading to superlinear policy growth.

Dynamic authorization automates many of these access control decisions, reducing the need for manual intervention. This has several benefits:

- **Lower administrative overhead**—eliminating the need for manually managing permissions and groups reduces administrative costs.
- **Reduced risk of over-permissioning**—accounts with permissions they no longer need are the source of many costly security breaches.
- **Reduced security insurance premiums**—many organizations buy costly insurance to protect against security breaches and ransomware. Better authorization practices can reduce premiums.
- **Fewer support tickets for access problems**—tickets that require IT to drop what they're doing to sort out a permissions problem take these
