HOW A POLICY TEMPLATE SHAPES TENANT CONTROL

Cedar offers native support for policy templates (https://docs.cedarpolicy.com/policies/templates.html), enabling policies to define reusable structures with parameters that can be specified during deployment.

C³ uses these templates to help tenants safely customize collaboration rules without writing free-form Cedar code. Each template provides a fixed structure with a few configurable inputs, such as allowed domains or project identifiers. When a tenant activates a template, the policy service fills in the parameters and creates a complete, schema-validated policy in the tenant's namespace.

Policy templates enable tenants to customize C³'s collaboration rules without writing free-form Cedar code. Each template defines a fixed policy structure with some configurable parameters. During deployment, ACME's policy service replaces these parameters to generate a complete, schema-validated Cedar policy within the tenant's namespace.

For example, ACME provides a template for controlling external sharing:

```
// Template: external-sharing
permit (
  principal,
  action == C3::"doc:share",
  resource in C3::Document
)
when {
  resource.owner.tenant == context.tenant_id
  && context.target_email_domain in ?allowed_domains
};
```

When a tenant admin configures this template, they supply parameter values like this:

```
{ "allowed_domains": ["example.com"] }
```
