of technicians.

16.8.4 Customer Collaboration Cloud (C³): Project-scoped roles in a multi-tenant platform

The Customer Collaboration Cloud (C³), introduced in chapter 13, is ACME's multi-tenant service that allows its tenants—customers of ACME—to collaborate directly with their customers on shared projects. Each tenant manages its own collaboration spaces, invites its own partners and clients, and sets project roles based on their business processes. ACME does not oversee these project roles, nor is it involved in the identity management between a tenant and its customers. Team composition changes as projects progress, and access requirements vary across project stages, departments, and stakeholder groups.

Instead of requiring tenants to create and manage accounts in C³, tenant organizations issue project-role credentials to participants they invite. These credentials include the tenant identifier, the project identifier, and the participant's role, such as project owner, contributor, reviewer, or finance approver. Many tenants distribute these credentials using OpenID4VC flows from their existing identity, CRM, or project management systems. Participants then present these credentials from their wallets when accessing C³.

When a participant opens a C³ project space, the PEP for the C³ service sends an attribute query requesting the necessary claims for policy evaluation: the tenant, project, and role. The verification layer confirms that the credential was issued by the correct tenant for that specific project, checks expiration and revocation status, and forwards normalized attributes to the PDP.

Policies in C³ can then enforce rules such as these:

- Project owners may manage workspace configuration and membership.
- Contributors may create and edit project artifacts.
- Reviewers may comment but not alter documents.
