the agent to query the policy system during planning.

The key idea is simple: rather than just asking “is this action allowed?”, the agent can ask broader questions like:

- Given my identity and the current context, which actions am I allowed to perform?
- For a given action, which resources can I access?

This shift transforms the policy system from a simple gate into a constraint system that actively guides planning.

ACME implemented this capability using Cedar’s Typed Partial Evaluation (TPE). As discussed in chapter 17, TPE enables the policy engine to evaluate policies even when part of the request is unspecified. By leaving one element of the PARC model open—such as the action or the resource—the policy engine can return the conditions under which a request would succeed. Figure 18.3 illustrates how this capability extends the policy-aware agent loop.
