18.6.2 Enforcing delegation at runtime

When a subagent attempts to invoke a tool, the request still flows through the policy-aware loop described earlier. The difference is that the policy enforcement point (PEP) now enriches the authorization request with delegation information. Figure 18.4 illustrates this interaction.

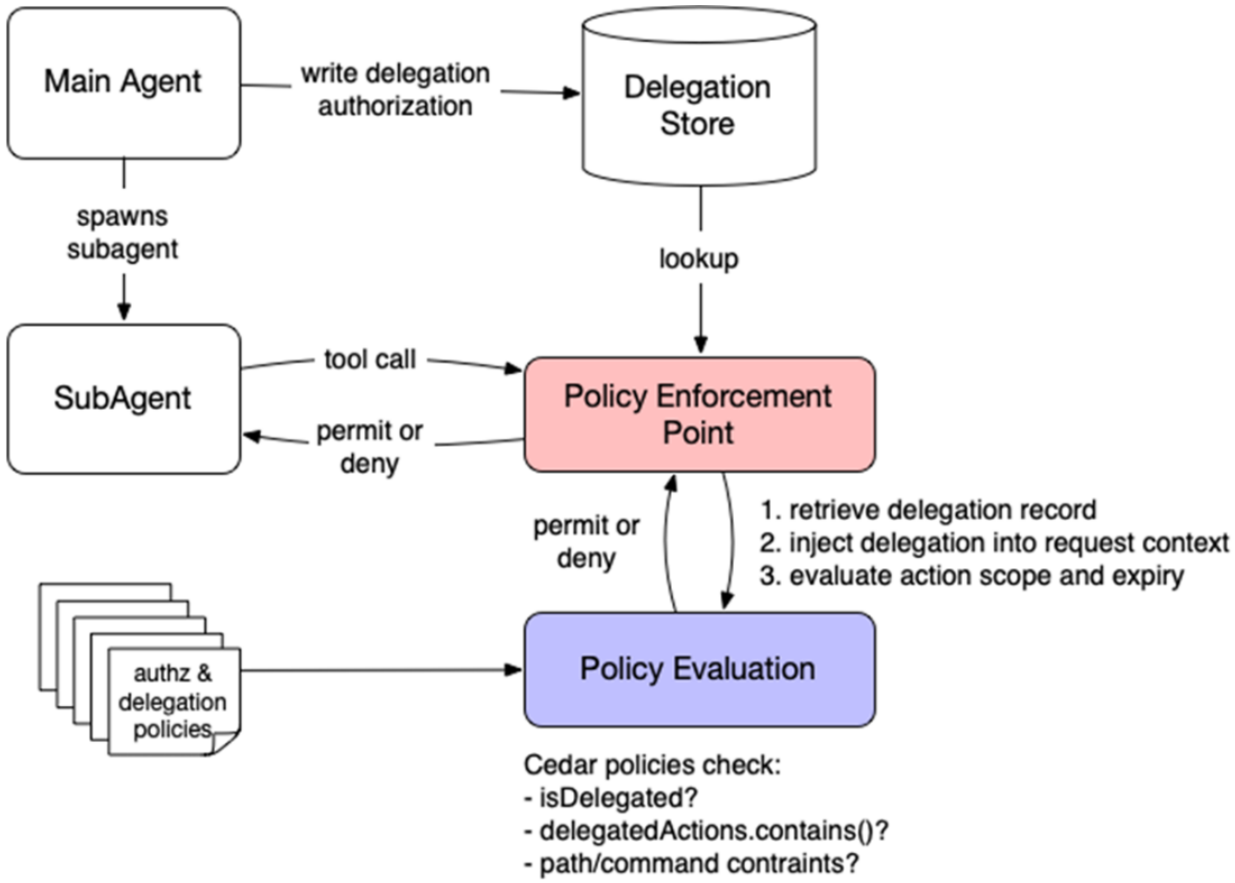

Figure 18.4 Policy enforcement for delegated agents. When a primary agent delegates work, a delegation record defines the scope of authority. When a subagent invokes a tool, the policy enforcement point includes the delegation data in the authorization request. The policy engine evaluates both the request and the delegation constraints before returning a decision.

At runtime, the process looks like this:

1. The subagent proposes an action.
2. The PEP retrieves the relevant delegation record.
3. The PEP constructs an authorization request that includes delegation data in the context.
