4. The policy engine evaluates the request using both the base policies and the delegation constraints.
5. The action is permitted or denied.

Conceptually, the request now includes an additional layer of context:

- **principal**—the subagent
- **action**—the requested operation
- **resource**—the target system or data
- **context**—task state, environment, *and delegation data*

This ensures that every action taken by a subagent is evaluated not only against general policy rules, but also against the specific limits of the delegated authority.

18.6.3 Policies that enforce delegation

Because delegation is represented as data, policies can enforce its constraints directly. A foundational policy ensures that the subagent is acting within the delegated identity:

```
permit (
    principal,
    action,
    resource
)
when {
    principal == context.delegation.delegate
};
```

Additional policies enforce the scope of the delegation itself:
