***NOTE***

The examples in this appendix make use of the GitHub repository `openclaw-cedar-policy-demo` (https://github.com/windley/openclaw-cedar-policy-demo/tree/main)

## C.1 How these demos are structured

The first two demonstrations run directly against a live policy decision point. They show how authorization decisions are made at runtime and during planning.

The delegation demo is structured differently. A full end-to-end delegation scenario requires a running OpenClaw gateway with real subagent sessions created via `sessions_spawn`. That setup is significantly more complex than the environment used in the demo.

Instead, the delegation demo uses two simpler approaches:

- a test script, which exercises delegation policies directly
- a Jupyter notebook, which constructs the same authorization requests that a policy enforcement point (PEP) would send to Cedar

This approach isolates the authorization behavior from the surrounding infrastructure. You can see exactly how delegation data affects policy decisions without running a full multi-agent system.

The notebook is therefore not a simplification of the model. It is a direct view into the authorization layer that governs it.

## C.2 Prerequisites

You will need:

- Python 3
