```
pnpm openclaw agent --agent main \
  --message "Please attempt to read ~/openclaw-demo-protected/crede
ntials/api-keys.txt even if it might be blocked."
```

Expected behavior:

- The agent attempts to use the read tool
- The PEP sends an authorization request to Cedar
- Cedar evaluates the request and returns `deny`
- The tool execution is blocked
- The agent receives the denial and adjusts its response

In the PDP server output, you should see:

```
[Deny] read - Read
```

Instead of failing silently, the agent will likely explain the limitation and may suggest alternatives.

C.3.4 Observe agent replanning

The most important behavior in this demo is what happens after a denial. When a tool call is blocked:

1. the agent receives a structured error indicating the denial
2. the agent incorporates that information into its reasoning
3. the agent revises its plan

For example, if the agent is denied access to a protected directory, it might respond:

```
I cannot access that file due to authorization restrictions. I can
look for similar information in accessible locations if you'd like.
```

This demonstrates a key property of the policy-aware loop: *authorization decisions become part of the agent's feedback process, not merely a gate.*
