```
forbid(principal is SubAgent, action, resource)
when {
  !(action in context.delegatedActions)
};
```

A deny by default policy provides a foundation:

```
forbid(principal is SubAgent, action, resource)
when {
  !(context.isDelegated)
};
```

Together, these ensure that delegation narrows authority rather than expanding it. The policies in the repository are worth reviewing.

C.5.3 Walk through the delegation notebook

To walk through the demo, start the notebook:

```
jupyter notebook demo/delegation-demo.ipynb
```

The notebook simulates the behavior of the policy enforcement point by generating authorization requests and evaluating them step by step. It walks through several scenarios.

- **Main agent baseline**—the main agent operates under base policies with full access.
- **Subagent without delegation**—All actions are denied, demonstrating default-deny behavior.
- **Read-only delegation**—A subagent is given read-only access to `/tmp/*`. Reads succeed, but writes and out-of-scope access are denied.
- **Scoped delegation behavior**—The notebook shows both permitted and denied actions, illustrating how delegation boundaries are enforced.
- **Command-constrained delegation**—A subagent may be restricted to commands matching a pattern such as `git *`, allowing controlled execution of specific tools.
