- **Expired delegation**—The notebook simulates time-based expiration. Since Cedar has no `now()` function, expiration is enforced by the PEP before the request is sent to the PDP.

These scenarios show a range of sub-agent actions that can be controlled through policy.

C.5.4 What to observe

As you run the delegation tests and step through the notebook, focus on four key ideas.

- **Subagents are distinct principals**—delegation policies apply only to them. The main agent continues to operate under the base policies and remains unaffected by delegation constraints.
- **Delegation is data, not policy**—the delegation record defines the scope of authority. It is not a policy. Policies evaluate the delegation data as part of the authorization request.
- **The PEP and PDP have different roles**—the policy enforcement point performs fast checks, such as rejecting requests with no delegation or expired delegation. The policy decision point evaluates the remaining request against Cedar policies.
- **Authority is always bounded**—delegation narrows it rather than expanding it. A subagent can perform only the actions explicitly delegated and only within the defined scope.

Together, these observations show that delegation remains fully governed by policy, ensuring that even as agents collaborate, every action remains within clearly defined and enforceable boundaries.

C.6 Wrapping up

The demonstrations in this appendix illustrate how authorization evolves as systems become more dynamic and agent driven.
