likely have customer enrollment processes that are more stringent than those required when signing up for a social media account.

Identity proofing is usually governed by an organization's processes and procedures. As such, the level of assurance is vulnerable to human error and thus outside the realm of technical confidence. One consequence of this is that proofing processes might be trusted internally, but are not something that can be easily shared without legal agreements. Organizations like the Trust Over IP Foundation (https://trustoverip.org/) and Ayra Association (https://ayra.forum/) are working to build industry-wide trust frameworks to make this easier and reduce the burden, inconvenience, friction, and cost of identity proofing, but this is still a work in progress.

### 3.4.3 Relationship context and boundaries

Enrollment defines the scope of the relationship. Enrollment is foundational to authentication and proving who someone is with a required level of assurance (LOA). But it also sets the stage for determining what they can do and under what conditions. For example, both bank customers and employees may be enrolled and proofed to IAL2, but their relationship with the bank is fundamentally different. The enrollment process defines the underlying context of the relationship that provides a foundation for strong authentication.

I recently created a supplier account with a large tech industry vendor. This account creation process was administratively controlled. I created an account, linked to me, and also one for my organization. My account had authentication credentials, but the organization's account did not. Only I could perform actions on behalf of the organization such as submitting invoices. My identity was only proofed to IAL1, but the organization's identity proofing involved proving I controlled the domain name for it. Figure 3.4 shows the relationships for this kind of account.
