

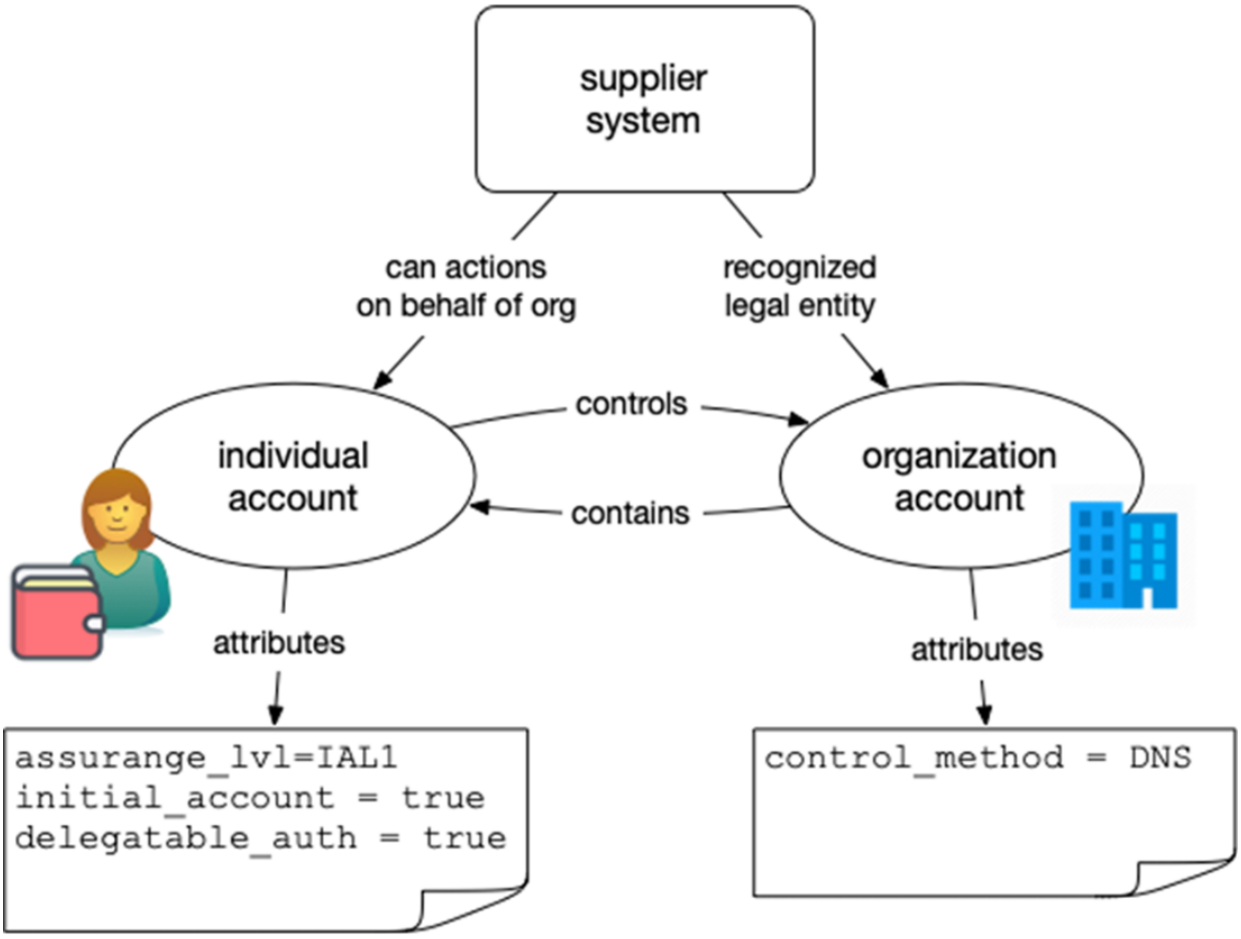

Figure 3.4 Enrollment relationships between an individual, their organization, and a supplier system. The individual account is authenticated and proofed to IAL1, while the organization account is established via domain control. Delegation rights originate from enrollment context and enable the individual to act on behalf of the organization within the supplier system.

The setup I performed during enrollment was in service of later authentication decisions. However, the nature of the information collected and the LOA that the enrollment process established were dictated by the access control needed by the supplier system. For example, I already had a customer account for this vendor, but this supplier account was different. There's no technical reason the same account couldn't be used, but the company had decided as a matter of policy to separate them. As the controller of the initial user account linked to the organization's account, I was granted default delegation rights that allowed me to add new users and grant rights to them. Exercising delegation rights was a matter of authorization, but the attributes (for example, `initial-account`) recorded during enrollment provided the required context.
